1 Introduction

The EXP-T program package is designed for the high-precision modeling of molecular electronic structure using the relativistic Fock space coupled cluster method (FS-RCC). Features and program components are listed in Sec. 1.1, 1.2 and 1.3.

The authors will be grateful for any comments or suggestions:

```
exp-t-program@googlegroups.com
https://groups.google.com/d/forum/exp-t-program
```

1.1 Electronic structure models

The EXP-T package does not include subroutines for solving the (Dirac-) Hartree-Fock equations and subsequent four-index transformation, so molecular integrals have to be imported from third party electronic structure packages. Currently EXP-T is interfaced to the DIRAC program package [1], thus getting access to the wide variety of Hamiltonians and property operators implemented therein.

Models available in EXP-T:

- single-point energy calculations with any point groups and (nearly) all Hamiltonians, implemented in DIRAC (4c-DC, X2Cmmf, 2c-ECP, non-relativistic);
- ground state energy calculations (the 0h0p sector): CCSD, CCSD(T), CCSDT-n (n=1,2,3), CCSDT models;
- the FS-CCSD method for excited states is implemented for the 0h1p, 1h0p, 1h1p, 0h2p, 2h0p, 0h3p Fock space sectors;
- FS-CC models for excited states accounting for triples (CCSDT-n (n=1,2,3), CCSDT) are implemented for the 0h1p, 1h0p, 1h1p, 0h2p, 0h3p Fock space sectors.

The summary of all electronic structure models implemented in the EXP-T program system is given below:

FS sector	CCSD	CCSD+T(3)	CCSDT-1	CCSDT-2	CCSDT-3	CCSDT
0h0p	+	+	+	+	+	+
0h1p	+	t	t	t	t	t
1h0p	+	t	t	t	t	t
1h1p	+	t	t	t	t	t
0h2p	+	t	t	t	t	t
2h0p	+	_	_	_	_	_
0h3p	$\mid t \mid$	t	t	t	t	t

"+" - implemented, "-" - not implemented, "t" - currently being tested

- "dynamic" energy denominators shifts as a solution of the intruder-state problem [2];
- Padé extrapolation to the zero-shift limit [3];
- finite-field transition moments calculations [4];

- quasidiabatization of SO-coupled states and SO extraction [2].
- «quasi-natural» spinors (NS) and natural transition spinors (NTS);
- one-electron properties via interface to the OneProp program by L. V. Skripnikov [5].

1.2 Features for high-performance calculations

- OpenMP parallelization (for shared-memory systems);
- parallel calculations on NVIDIA GPUs using the CUDA platform [6].

1.3 Program components

- expt.x Input processing + all CC calculations.
- heffman.x Manipulations with effective Hamiltonian matrices: Padé extrapolations, finite-field transition moments calculations, quasidiabatization of SO-coupled states.
- expt2pam.x Tool for convenient basis set and ECP input.

1.4 Citation

We kindly ask you to acknowledge any use of the EXP-T program system that results in published material using the following citation:

- The 0h3p Fock space sector: [8]
- Finite-field transition matrix elements (general): [4]
- Finite-field transition matrix elements (the $0h0p \rightarrow 1h1p$ excitations): [9]
- Spin-orbit coupling calculations: [2]
- Dynamic denominator shifts (real): [2]
- Dynamic denominator shifts (imaginary, or their real simulation): [10]
- Padé extrapolation of effective Hamiltonian series: [3]

1.5 Credits

EXP-T is based on ideas and design solutions of the suite of FS-CC programs written by Ephraim Eliav and Uzi Kaldor.

2 Installation from source code

2.1 Compiling EXP-T

EXP-T is currently oriented at Unix-like operating systems.

Tools required for compiling the EXP-T package from source code:

• C and Fortran compilers. Currently supported compiler systems are

```
gcc/gfortran GNU compilers icc/ifort Intel compilers
```

• cmake version 3.0.2 or higher and make utilities:

```
https://cmake.org/
https://www.gnu.org/software/make/
```

Optional dependencies:

- Implementation of the BLAS/LAPACK linear algebra libraries (OpenBLAS or Intel MKL are recommended);
- NVIDIA drivers and CUDA Toolkit are required to perform parallel calculations on GPU: https://www.nvidia.com/Download/index.aspx?lang=en-us https://developer.nvidia.com/cuda-toolkit

Download the EXP-T source code as a *.tar.xz file and unpack it:

```
tar xvf expt-X.Y.Z.tar.xz
```

Go to the EXP-T home directory, create the build directory and make it the current working dir:

```
mkdir build
cd build
Compilation (Intel compilers):
CC=icc FC=ifort cmake ..
make
Compilation (GNU compilers):
CC=gcc FC=gfortran cmake ..
make
```

We recommend specifying compilers explicitly (since the default C compiler may be something other than gcc).

The CMake utility will try to locate BLAS/LAPACK libraries on your computer; in case of multiple implementations found you will be asked to choose one of them. If there are no pre-installed libraries on your machine, the internal OpenBLAS will be compiled and linked to EXP-T.

When using Intel MKL together with GNU compilers, you will probably need to explicitly specify the path to the MKL home directory by setting the environment variable MKLROOT. For example:

export MKLROOT=/opt/intel/mkl

In case of successful compilation, the executable file expt.x will appear in the build directory.

We strongly recommend that compilation is followed by testing (see Sect 2.4).

Do not forget to add the directory containing the binaries to the PATH environment variable!

2.1.1 Compiling on Mac OS X

The default C compiler for Mac OS X is clang; this compiler was not tested, so we strongly recommend to use gcc instead:

```
CC=gcc FC=gfortran cmake ...
```

We strongly recommend not to use GNU compilers installed with Homebrew. Instead, download the GNU compilers suitable for your version of Mac OS X from:

```
http://hpc.sourceforge.net/
```

In order to use a BLAS/LAPACK implementation other than the one attached to the EXP-T package, you can use the following manual:

https://pheiter.wordpress.com/2012/09/04/howto-installing-lapack-and-blas-on-mac-os/However, the Netlib implementation described there can perform several times slower than the OpenBLAS implementation included in EXP-T.

2.2 Compiling with CUDA

Compilation of EXP-T does not require the user to have a CUDA-compatible GPU device. If the CUDA toolkit is missing, the CUDA code will simply be excluded from the compilation process.

EXP-T is adapted for parallel calculations on NVIDIA GPUs (the CUDA technology [6]). Notes:

- 1. At the moment, the OpenMP+CUDA hybrid model as well as multi-GPU support is not implemented. Only one GPU can be used for calculations.
- 2. non-professional GPUs for gaming are not suitable for CUDA calculations (except for Kepler cards).
- 3. CUDA code in EXP-T was tested only for CUDA 9.1 and 10.0.
- 4. Only Intel and GNU compilers were tested for compatibility with CUDA.

To compile EXP-T with CUDA:

- 1. Make sure your graphics card supports CUDA. CUDA-compatible GPUs are listed here: https://developer.nvidia.com/cuda-gpus
- 2. Install proprietary NVIDIA drivers (not the nouveau driver!). https://www.nvidia.com/Download/index.aspx?lang=en-us. For Linux you can find drivers in your distribution's repository.
- 3. Install CUDA toolkit https://developer.nvidia.com/cuda-downloads or from distribution's repository.

- 4. Make sure that all drivers and CUDA toolkit are installed and work correctly. Compile the test suite in the samples directory of the CUDA home directory and run some of them. The most important are the tests employing the CUBLAS linear algebra library.
- 5. Compile EXP-T as described in Sec. 2.1. All CUDA tools will be located automatically by CMake.
- 6. Make sure that the results produced by EXP-T do not depend on the use of CUDA.

2.3 Troubleshooting

This section describes the most common problems which can occur during the compilation process. In case of any questions or problems, please don't hesitate to contact us. Don't forget to attach the output file (in case of problems with calculations) or the file with the output of the make VERBOSE=1 command (in case of problems with compilation).

Google Groups:

```
https://groups.google.com/d/forum/exp-t-program
```

E-mail:

```
exp-t-program@googlegroups.com
```

2.3.1 Outdated version of CMake

We highly recommend using CMake version 3.0.2 or higher, otherwise, problems may occur when building the internal OpenBLAS. The following command will show what version of CMake is installed:

```
cmake --version
```

If CMake version is lower than 3.0.2, download the binary distribution from their official website https://cmake.org/download/. After installation do not forget to add the directory containing the CMake binary files to the PATH environment variable.

Installation of CMake binary files does not require root privileges.

2.4 Testing

Test suite is located in the test directory. The testing system is written in the Python programming language (must be pre-installed on your machine). Either Python 2 or Python 3 can be used.

In order to run the testing suite, change the working directory to test and run the test.py script:

```
cd test
python test.py
```

It is also possible to run an abridged version of the testing suite, that includes only the most important tests. In that case specify the additional argument quick:

```
python test.py quick
```

3 Running EXP-T

See Sec. 6 for a description of an additional utitily programs included in the EXP-T package.

A typical calculation consists of two sequential steps: (1) SCF and integral transformation within DIRAC and (2) CC calculation within EXP-T.

3.1 Precomputing spinors and molecular integrals: DIRAC step

The interface to DIRAC was tested only for the DIRAC17 and DIRAC18 releases. DIRAC stores transformed molecular integrals in the following binary files:

MRCONEE information about SCF calculation, symmetry, occupation numbers, one-electron integrals;

MDCINT symmetry-unique nonzero two-electron integrals;

MDPROP one-electron property integrals.

Run DIRAC and save the files containing the transformed integrals to the working directory using the --get option:

```
pam --noarch --mol=<mol-file> --inp=<inp-file> --get="MRCONEE MDCINT MDPROP"
```

If DIRAC starts in parallel mode (MPI), it is necessary to choose the transformation algorithm "scheme 4". By default, DIRAC uses the "scheme 6" algorithm which produces multiple MDCINT files [11] and currently EXP-T requires that all integrals are stored in a single file. In order to accomplish this, add the following lines to the DIRAC input file:

```
**MOLTRA
.SCHEME
4
```

To calculate approximate transition moments and intensities without resorting to the finite-field scheme transformed dipole moment integrals are required. We recommend explicitly ask DIRAC to calculate and transform these integrals by adding the <code>.PRPTRA</code> and <code>.DIPOLE</code> keywords to DIRAC input files:

```
**MOLTRA
.PRPTRA
.....
**PROPERTIES
.DIPOLE
```

If the molecular-mean-field X2C Hamiltonian (X2Cmmf) was used at the DIRAC stage, one must specify the x2cmmf flag in the EXP-T input file! (see also page 19).

3.2 Coupled cluster: EXP-T step

Run an EXP-T job using the following command:

```
expt.x [options] <input-file>
```

The EXP-T output (including error messages) is flushed to the UNIX standard output (stdout). Use the output redirection operator ">" in case of long time calculations:

```
nohup expt.x <input-file> > <output-file> &
```

Examples of DIRAC and EXP-T input files are given in Sec. 5.

3.3 Command-line arguments

Use the expt.x --help command to print a list of available command-line arguments:

Usage: expt.x [OPTION...] <input-file>
expt -- A Fock-Space Multireference Relativistic Coupled-Cluster Program

-n,no-clean	Do not clean scratch directory on exit
	(use this option to keep cluster amplitudes etc)
-s,scratch=PATH	Path to scratch directory (default: ./scratch)
-?,help	Give this help list and exit
usage	Give a short usage message and exit
-V,version	Print program version and exit

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

Please report bugs to <exp-t-program@googlegroups.com>.

4 Input files syntax and keywords

See Sec. 6 for the description of additional utitily programs included in the EXP-T package.

The input file format may change in future versions.

The EXP-T input file contains a list of instructions. Each instruction is placed on a separate line and consists of a keyword and a list of arguments. Single-line comments start with '#' and continue until the end of the line. Input is case insensitive. Examples of EXP-T input files are given in Sec. 5. Molecular geometry, basis set etc have to be described only once in the DIRAC input files at the molecular integrals calculation stage (not in EXP-T input files).

The detailed description of the keywords used in the EXP-T input file is provided below. For convenience, keywords are grouped into several sections. The order of keywords in the input file can be arbitrary.

General

title optional comment.

Syntax: title <quoted-string>

Default: no title

Example: title "my first ccsd calculation"

print print level.

Syntax: print (low || medium || high || debug)

Default: print medium

degen_thresh energy levels are considered as degenerate if the energy gap between them is lower than degen_thresh.

Syntax: degen_thresh <real thresh>

Units: atomic
Default: 1e-8

Model

sector specifies the target Fock space sector. To the moment the 0h0p, 0h1p, 1h0p, 1h1p,

0h2p, 2h0p, 0h3p FS sectors are implemented (h - holes, p - particles).

Syntax: sector <integer H>h<integer P>p

Default: sector 0h0p (vacuum)

model CC model (approximation to the cluster operator).

Default: model ccsd

Notes:

• Keywords ccsd(t) and ccsd+t(3) are equivalent.

- The codes implementing the CCSD+T(3), CCSDT-n and CCSDT models in the non-trivial sectors and all CC models in the 0h3p sector are experimental (currently being tested), to be used with care.
- The current implementation of the CCSD(T) model for the 0h0p sector is not very computationally efficient.
- The CCS and CCD models are implemented simply by setting all T_2 (CCS) or T_1 (CCD) amplitudes to zero, this does not make computation faster, and exist primarily for the purposes of testing and debugging.

spinor occupation numbers. This keyword can be used to setup calculations with a "high-spin" vacuum state [12]. This keyword is alternative to the occ_irreps keyword (see below).

Syntax: occ <list of the 0 and 1 digits separated by spaces>

Default: occupation numbers are read from MO integrals files

Example: 5 electrons and 10 spinors:

occ 1 1 0 0 0 1 1 1 0 0

CC calculations with high-spin vacuum states were tested for the 0h0p FS sector only.

occ_irreps overall number of electrons in each irrep. Overall irrep occupations are ignored if occupation numbers of individual spinors are given (by the occ keyword, see above).

Syntax: occ_irreps <list of integers>

Default: occupation numbers are read from MO integrals files

Active space

nacth/nactp active (i.e. valence) space specification (by the overall number of active spinors, regardless of their symmetry). This method of configuring the active space is recommended.

- nacth number of highest occupied spinors (active holes)
- nactp number of lowest virtual spinors (active particles)

It is convenient to setup the active space by the nacth/nactp keywords when exploring electronic states of molecules in a range of geometries (potential energy surfaces, transition moment functions etc). Using the nacth/nactp keywords one can specify either overall number of active spinors (holes or particles) or number of active spinors in each irreducible representation.

```
Syntax:
        nacth <integer dim>
         nactp <integer dim>
         nacth <pairs irrep:number-of-spinors>
         nactp <pairs irrep:number-of-spinors>
```

Default: nacth 0, nactp 0 (no active spinors).

Example: consider the low-lying electronic states of the La atom. Those are dominated by the $6s^n5d^m$ configurations, generating even electronic states. So it seems reasonable to include the $6s_{1/2}$, $6d_{3/2}$ and $6d_{5/2}$ atomic spinors of the La³⁺ cation into the active space and achieve target electronic states in the 0h3p Fock space sector. In order to make the input file easy to read, one can use two sequential nactp directives, one for the "negative" projections of m_i , and one for the "positive" ones:

```
nactp [1/2g+]:3 [3/2g+]:2 [5/2g+]:1
nactp [1/2g-]:3 [3/2g-]:2 [5/2g-]:1
```

One can extend the scope of achievable electronic states by inclusion of the 6p and 4f spinors:

```
nactp [1/2u+]:4 [3/2u+]:3 [5/2u+]:2 [7/2u+]:1
nactp [1/2u-]:4 [3/2u-]:3 [5/2u-]:2 [7/2u-]:1
```

active (i.e. valence) space specification by energy range. Active spinors must have active

one-electron energies in the range $\varepsilon_i \in [\varepsilon_{min}; \varepsilon_{max}]$ (regardless of their symmetry). Setting the active space using the active keyword is convenient only for atomic

calculations.

Syntax: active energy <real eps_min> <real eps_max>

Default: no active spinors

Example: active energy -1.0 5.0

Properties

do not perform symmetric orthogonalization of model vectors. Orthogonalized nohermit model vectors are used only to calculate properties and approximate density matrices; matrices of effective Hamiltonians flushed to HEFF files (see Sec. 6.1) remain non-Hermitian.

Syntax: nohermit

Default: "hermitization" is enabled.

enable calculations of the model-space approximations to transition dipole momstdmments (wavefunctions are represented by model vectors) [13, 14, 9]). To avoid huge outputs, use option **nroots** to restrict the set of target roots.

Note that left model vectors are used in bra:

$$d_{if,\eta} = \langle \tilde{\psi}_i^{\perp \perp} | d_{\eta} | \tilde{\psi}_f \rangle \qquad \eta = x, y, z$$

and if "hermitization" of the effective Hamiltonian matrix is disabled, the TDM matrix will be (normally slightly) non-Hermitian $(|d_{if}| \neq |d_{fi}|)$.

This approach typically overestimates transition moments by 30-50%, hence we recommend using it only for semiquantitative estimations, e.g. detection of the most intensive transitions and discerning between 0^+ and 0^- states (such transitions are strictly forbidden).

Syntax: mstdm
Default: disabled.

 ${\tt mdprop}$

enable calculations of the model-space approximations to arbitrary properties presented in the DIRAC's MDPROP unformatted file. To avoid huge outputs, use option nroots to restrict the set of target roots. To be used for semiquantitative estimations only.

Syntax: mdprop "property-name>" [transpose]

Default: disabled.

Example: calculation of x,y,z-components of transition moments.

mdprop "XDIPLEN"

mdprop "YDIPLEN"

mdprop "ZDIPLEN"

txtprop

enable calculations of the model-space approximations to arbitrary properties. Property matrix is loaded from two formatted files. To avoid huge outputs, use option nroots to restrict the set of target roots. To be used for semiquantitative estimations only.

Syntax: txtprop <string file_re> <string file_im> [transpose]

Default: disabled.

Example:

mdprop PropIntsRe.txt PropIntsIm.txt

The code for properties is currently experimental; please, we kindly ask you to report all failures and obviously incorrect results.

natorb

calculation of "quasi-natural" spinors (NS) and transition spinors (NTS).

Note: density matrices $d_{pq}^{IJ}=\langle \tilde{\psi}_I^{\perp\perp}|a_p^{\dagger}a_q|\tilde{\psi}_J\rangle$ are constructed with model vectors instead of true wavefunctions.

Syntax: natorb [<rep>:<state> | <rep1:state1>-<rep2:state2>] ...

Electronic states are given by the <rep>:<state> pair, where:

<rep> name of representation in square braces. See Sec. C for the list of representation names used in EXP-T.

 \langle state \rangle sequential number of the state in the irrep (1, 2, ...).

Pair of electronic states separated by hyphen shows that NTS between these states are to be calculated. You can ask EXP-T to calculate NS and NTS for arbitrary number of states (or pairs of states).

Default: calculation of NS and NTS is disabled.

Examples:

• NS for the ground and the first excited states of the RaCl molecule:

natorb [1/2+]:1 [1/2+]:2

• NTS for the $(1)0^+ - (2)0^+$ transition in the RbCs molecule:

natorb [0]:1-[0]:3

(note that in the latter example the [0]:2 state is excluded, since it is the $(1)0^-$ state).

Iterative solution and convergence

arith allows one to force EXP-T to use the complex arithmetic everywhere.

Syntax: arith complex

nroots specifies the number of roots (electronic states) of interest in each irrep (in the target Fock space sector). Model vectors analysis will be performed only for the nroots lowest states.

Syntax: nroots <pairs irrep:number-of-roots>

Default: all roots are of interest.

Example: consider the electronic states of the RbCs molecule, corresponding to the first three dissociation limits (see, for example, [2, 15] and references therein). In the Hund's case a these electronic states are $X^1\Sigma^+$, $a^3\Sigma^+$, $b^3\Pi$, $A^1\Sigma^+$, $c^3\Sigma^+$, $B^1\Pi$. In the Hund's case c these states are classified according the projection of the total electronic angular momentum and can be rearranged as follows: $(1-3)0^+$, $(1-3)0^-$, (1-4)1, (1)2 states. The names of irreps used in EXP-T are given in Appendix C (the point group of RbCs is $\overline{C_{\infty v}}$). All output and analysis of model vectors will be restricted to these 11 states using the following command:

```
nroots [0]:6 [1+]:4 [1-]:4 [2+]:1 [2-]:1 (note that as in DIRAC 0^+ and 0^- states belong to the same irrep).
```

roots_cutoff specifies the upper energy bound for the electronic states to be analyzed and printed. Model vectors analysis and properties calculations will be performed only for the states with energy lower than roots_cutoff. Allowed units of energy are eV, cm⁻¹ and Hartrees.

Syntax: roots_cutoff <real max_energy> (ev || cm || au)

Default: all roots are of interest.

Example: roots_cutoff 30000 cm

maxiter maximum number of iterations allowed to solve the CC equations.

Syntax: maxiter <integer max>

Default: maxiter 50.

conv specifies the requested convergence threshold (in amplitudes):

$$\left| |t_K^{(n+1)}| - |t_K^{(n)}| \right| < conv \quad \forall K \quad \to \text{converged}$$

Syntax: conv <real thresh>

Default: 1e-9.

div_thresh specifies the divergence threshold (in amplitudes). Solution of amplitude equation is diverged if for some t_K holds:

$$\left| |t_K^{(n+1)}| - |t_K^{(n)}| \right| > div_thresh \quad \to \text{diverged}$$

May be useful if few initial steps of the iterative solution are divergent.

Syntax: div_thresh <real thresh>

Default: 1e+3.

diis enables the DIIS extrapolation technique [16, 17].

Syntax: diis [(off || <integer dim>)]

Disable DIIS: diis off

Enable DIIS for triples: diis triples

Default: diis 10 (DIIS is enabled for singles and doubles, disabled for triples)

It is highly recommended to enable DIIS for triples if the CCSDT-n or CCSDT models are employed.

damping enable damping in the given FS sector. Amplitudes obtained at the n-th step will be mixed with amplitudes from the (n-1)-th step using the damping factor α :

$$T^{(n)'} = \alpha T^{(n-1)} + (1 - \alpha)T^{(n)}$$

Damping can aid the convergence of equations in some non-pathological cases (when the lack of convergence is caused by amplitude oscillations rather than intruder states). Note that in other cases damping can significantly slow down convergence.

Syntax: damping <H>h<P>p <integer last_step> <real factor>

<H>h<P>p
FS sector in which these damping parameters will be applied

last_step at which iteration damping will be disabled

factor damping factor α . Can be negative.

Default: disabled in all sectors

Example: damping 0h2p 100 0.5

shifttype indicates which formula for denominator shifts should be used [2, 3]. See Sec. ?? for details.

shifttype is the same for all FS sectors. If shifttype is not equal to none, you must specify the shift parameters for at least one FS sector (see keyword shift; except for 0h0p).

Syntax: shifttype (none || real || realimag || imag || taylor)
Possible values:

none no shift

real real shift

$$D_K' = D_K + S \left(\frac{S}{D_K + S}\right)^n \tag{1}$$

realimag real simulation of imaginary shift [10]

$$D_K' = D_K + \frac{S^2}{D_K} \left(\frac{S^2}{D_K^2 + S^2} \right)^n \tag{2}$$

imag imaginary shift [10]

$$D_K' = D_K + iS \left(\frac{|S|}{|D_K + iS|}\right)^n \tag{3}$$

taylor extrapolated intermediate Hamiltonian-like shift [18]

$$D_K' = (D_K + S) \frac{\left(1 - \frac{S}{D_K + S}\right)}{1 - \left(\frac{S}{D_K + S}\right)^{n+1}} \tag{4}$$

Default: shifttype none

Shift is never applied in the 0h0p sector!

orbshift indicates the use of sector-universal shifts. For given "orbital" shift s and cluster amplitude t_K the resulting shift S is defined as

$$S = n_v(t_K) \times s/2$$

where $n_v(t_K)$ is the number of valence indices of t_K . Thus, it is enough to set only one parameter, s, for all sectors and cluster operators of arbitrary excitation rank. You can also set the attenuation parameter n, see eqs. (1) and (4).

Syntax: orbshift [<integer power default 3>] <real shift s>.

Notes:

- The shift directive disables orbital shifts.
- The shifttype directive is required.

Example:

```
shifttype real orbshift 3 -0.3 # power == 3, s = -0.3 # shifts for T2 amplitudes will be: # 1 valence index: S = s/2 = -0.15 # 2 valence indices: S = s = -0.3 # 3 valence indices: S = 3*s/2 = -0.45
```

shift sets the denominator shift parameters in the $n_h h n_p p$ FS sector.

 $\label{lem:shift_S1> (real shift_S2> [(real shift_S3>)]} shift < H>h<P>p < int n> (real shift_S3>) |$

n attenuation parameter (see eqs. (1) and (4));

shift_S1 shift value for the $S_1^{n_h h}$ $n_p p$ cluster operator (singles). Must be omitted in the 2h0p and 0h2p FS sectors. It is recommended to set $\mathtt{shift_S1}{=}0.0$ in the 1h1p sector, unless you really understand the consequences of using nonzero values. Note that $\mathtt{shift_S1}$ value in this sector does not affect the resulting energies;

shift_S2 shift value for $S_2^{n_h h \ n_p p}$ (doubles);

shift_S3 shift value for $S_3^{n_h h n_p p}$ (triples). Must be used only for CC models including non-perturbative triples.

Default: n = 3, all shifts = 0.0

Examples:

shift 0h1p 3 -0.3 -0.6 -0.9

shift 0h1p 3 -0.6

shift 1h1p 4 0.0 -0.5

reuse indicates that sorted integrals and cluster amplitudes from the previous calculation should be reused. Cluster amplitudes will be used as an initial guess. If EXP-T fails to locate the files containing amplitudes, they will be recalculated.

Syntax: reuse <list-of-arguments>

Possible values of arguments:

Default: no reuse

Note: files with converged amplitudes are flushed to the scratch directory after each calculation (see also Appendix B). To prevent the deletion of files with amplitudes or integrals it is necessary to use the --no-clean command-line option.

Example: reuse integrals 0h0p 0h1p

flush

indicates that cluster amplitudes must be flushed to disk every N iterations. Can be useful for very time-consuming calculations with poor convergence. Allows one to change the convergence acceleration strategy.

Syntax: flush <integer N> iter

Default: no flush.

Example: flush 5 iter

skip

indicates which sectors will be skipped in the FS-CC calculation. Can be useful in very costly calculations (like CCSDT) in order to avoid recalculation of the first step in already converged sectors. To be used with the reuse option.

Syntax: skip <list-of-sector-symbols>

Default: no skip.

Example: skip 0h0p 0h1p

Interfaces

integrals sets paths to files containing transformed molecular integrals.

Syntax: integrals <string "1-el int-s"> <string "2-el int-s"> [<string "properties int-s">]

Arguments:

- one-electron integrals file;
- two-electron integrals file;
- properties transformed integrals file.

Default: integrals MRCONEE MDCINT MDPROP

Example: integrals ../MRCONEE-Cinfv ../MDCINT-Cinfv /home/user/MDPROP

x2cmmf

since DIRAC's unformatted files do not contain any information about the relativistic Hamiltonian used, the x2cmmf flag must be used if the molecular-mean-field X2C Hamiltonian (X2Cmmf) was employed at the DIRAC stage.

Syntax: x2cmmf

Memory management

memory

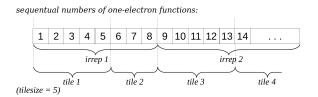

specifies the amount of memory that EXP-T can use for the job (just for *dynamically* allocated memory).

Syntax: memory <real size> (mb || gb)

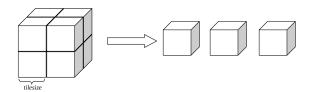

Min value: 10 Mb

Default: memory 1024 mb (1 Gb)

tilesize the whole set of one-electron functions (spinors or spin-orbitals) is divided into blocks: (1) by irrep; (2) then into sub-blocks with size not exceeding tilesize (actually the same as "tiles" in NWChem-TCE):

The N-dimensional arrays of integrals and amplitudes (tensors) also turn out to be divided into blocks containing $\sim (tilesize)^N$ elements:

tilesize must be large enough to place at least one N-dimensional array of size $(tilesize)^N$ in RAM. We recommend using as large tilesize as possible, otherwise memory management overheads can become enormous. However, it may be useful to decrease the tilesize parameter in cases of insufficient RAM or threaded execution (sufficient granularity of arrays leads to better dynamic load balancing among OpenMP threads).

Syntax: tilesize <integer size>

Default: tilesize 100

disk_usage indicates which data should be stored on the disk. Note that very intensive disk usage will slow down calculations; however, disk usage is unavoidable in case of large tasks.

Syntax: disk_usage <integer mode>

Possible values of <mode>:

- 0 all data is stored in RAM;
- 1 tensors of rank ≥ 6 are stored on disk (T_3 amplitudes etc);
- 2 tensors of rank ≥ 6 and $\langle pp||pp\rangle$ (4 particles) two-electron integrals are stored on disk;
- 3 tensors of rank ≥ 6 , $\langle pp||pp\rangle$ and $\langle *p||pp\rangle$ (3 particles) two-electron integrals are stored on disk;
- 4 the same as 3, + compression of all data. Is suitable for extremely large tasks only.

Default: $2 - \langle pp || pp \rangle$ and tensors of rank ≥ 6 are stored on disk.

compress

enables compression of all data written to disk. The LZ4 algorithm [19] is employed (the fastest decompression to the date). Compression can slow down calculations slightly (depends on disk), but the disk space used can be reduced dramatically (up to 3 times).

Syntax: compress

Default: disabled (except for disk_usage=4)

Parallel execution

nthreads

number of OpenMP threads. Note that scaling with respect to number of threads is much better for large tasks (400+ spinors).

Syntax: nthreads <integer n_omp_threads>
Default: nthreads 1 (sequential execution).

At the moment parallelization is not used at the integral sorting stage, hence OpenMP can accelerate only the amplitude equations solution stage.

openmp the same as nthreads.

cuda

enables parallel calculations on NVIDIA GPU (only a single GPU is supported at the moment). Requires nthreads 1 (the OpenMP+CUDA hybrid model is not implemented yet).

Syntax: cuda

Default: CUDA disabled.

Running typical calculations 5

The input and output files discussed in this section can be found in the examples directory of the EXP-T distro.

Ground state energy with CCSD: CO molecule 5.1

```
For input/output files see examples/CO_ccsd
```

```
Consider the calculation of the CCSD correlation energy of the CO molecule in the cc-pVDZ
[25] basis set.
   DIRAC input files:
   (CO.mol)
DIRAC
CO molecule, R = 2.132 bohrs
symmetry C1
    2
         6.
               1
          0.0
                    0.0
                              0.0
LARGE BASIS cc-pVDZ
         8.

*END OF INPUT
   We run DIRAC with the following command:
```

```
pam --inp=TRA --mol=CO --get="MRCONEE MDCINT"
```

Note that the --get option is used so that pam exports the transformed molecular integrals (stored in the MRCONEE and MDCINT files) from DIRAC's scratch directory to the working directory.

In some cases, it can be convenient to rename the files containing the integrals (this is not mandatory):

```
mv MRCONEE MRCONEE-C1
mv MDCINT MDCINT-C1
   Now the EXP-T input file input-C1 is set up:
# CO molecule, CCSD/cc-pVDZ
# nonrelativistic, symmetry C1
# task title (of type "string")
title "CO/CCSD/cc-pVDZ"
# print level, default medium
print medium
# max number of iterations
maxiter 30
# convergence threshold (by cluster amplitudes)
conv 1e-9
# target Fock space sector
sector OhOp
# CC model: ccsd, ccsdt-1, etc
model ccsd
# import integrals from
integrals MRCONEE-C1 MDCINT-C1
To run EXP-T, enter:
expt.x input-C1
```

The string with the correlation energy can be found at the end of the output. Note that by default EXP-T flushes all output simply to stdout.

```
SCF reference energy = -112.820480227130

CCSD correlation energy = -0.298117912040

Total CCSD energy = -113.118598139170
```

5.2 Simple atomic FS-CCSD calculation: the Pb atom

For input/output files see examples/Pb_fs_ccsd

We now turn to simple atomic relativistic calculations employing the FS-CCSD approach. Since wave functions of most low-lying electronic states of one-electron atoms and atomic ions are effectively single-reference, it is not very interesting to apply the multireference methodology. In contrast, electronic states of the "two-electron" atoms can hardly be simulated using any other approaches except those based on the multireference wave functions. Consider for example the $6s^26p^2$ low-lying states of the Pb atom. The reference state will be Pb²⁺ $6s^2$, and one should select 6p-spinors as the active ones (overall 6 spinors).

Pb atom is a purely relativistic system, and one should use four-component Hamiltonian or relativistic pseudopotential approach. The latter allows one to incorporate bulk of the Breit interaction and QED corrections. Here the semilocal valence version of the N.S. Mosyagin's RECP for Pb is used (see [26] and references therein).

Input file for the FS-CCSD calculation will be as follows:

```
sector 0h2p
nactp 6
maxiter 500
memory 110 gb
conv 1e-7
disk_usage 0
nthreads 8
model ccsd
```

After the FS-CCSD calculation is finished, one can compare the calculated FS-CCSD excitation energies of Pb with their experimentally measured counterparts (7819, 10650, 21458 and 29467 cm⁻¹, respectively [27]):

		Re(eigenvalue)	Rel eigv, eV	Rel eigv, cm-1	deg	symmetry
@	1	-0.8258538771	 0.000000000	0.000000	1	0g
@	2	-0.7916687782	 0.9302239316	7502.761992	3	0g 1g+ 1g-
0	3	-0.7784232250	 1.2906537953	10409.824894	5	0g 1g+ 1g- 2g+ 2g-
0	4	-0.7298818976	 2.6115306047	21063.414836	5	0g 1g+ 1g- 2g+ 2g-
0	5	-0.6892150215	 3.7181326781	29988.762480	1	0g

The remaining error can be significantly reduced by inclusion of triple excitations [7].

5.3 Electronic states of the HgH²⁺ molecular ion. Energy denominators shifts technique

For input/output files see examples/HqH2+_shifts

In almost every problem involving the exploration of potential energy surfaces using the FS-CC method in a fairly wide range of internuclear distances, the intruder state problem arises. The presence of intruder states usually manifests itself as (but does not not simply arise from!)

the appearance of small energy denominators in amplitude equations (see Sec. ?? for details); the presence of small denominators makes the iterative procedure unstable. A straightforward solution of the intruder-state problem can be obtained by modifying (shifting) all energy denominators in the problematic Fock space sector(s) in such a way that the shifts are significant for ill-defined (nearly zero or positive) energy denominators and remain negligibly small for large negative denominators [2, 3]. Note, however, that this does not imply any modification of the right-hand side of the amplitude equations and, thus, introduces an additional (although controllable) approximation.

The denominator shift technique is implemented in EXP-T; different formulas are available (see Sec. 4, keyword shifttype). The example discussed below employs the simplest *real* shifts.

Consider the ${\rm HgH^{2+}}$ molecular ion at R=2.0 bohr. The FS-CC equations cannot be solved at all without using denominator shifts. Let the active space be comprised of the 8 lowest virtual spinors. The EXP-T input file will look like this:

```
# Test:
# (1) HgH2+ ion, FSCC scheme: HgH3+ -> HgH2+
# (2) hamiltionian: 2-comp gatchina ECP
# (3) symmetry Cinfv
# (4) sector Oh1p
title "Test HgH3+ -> HgH2+/gatchina ECP/Cinfv"
maxiter 200
conv 1e-9
active -10 -0.5
sector Oh1p
# import integrals from:
integrals MRCONEE-Cinfv MDCINT-Cinfv
# shifts of denominators:
# real shift:
shifttype real
# shift parameters:
# 1. <n> -- attenuation parameter (here: 3)
# 3. <S1> -- shift for all S1 amplitudes (here: -0.5)
# 3. <S2> -- shift for all S2 amplitudes (here: -1.0)
shift 0h1p 3 -0.5 -1.0
```

Approaches to the selection of shift parameters are discussed in [2, 3]. You can also perform Pade extrapolation of the series of effective Hamiltonian matrices to the zero shift limit in order to minimize distortions introduced by the shift [3] (see also Sec. 6.1).

5.4 Finite-field transition dipole moments calculations: Rb atom

For input/output files see examples/Rb_atom_TDMs

See [14, 28, 4] for detailed discussions on the finite field technique (FF) for transition dipole moments. The algorithm for any FF calculation is as follows:

- solve the HF problem for the non-perturbed Hamiltonian (no external fields);
- transform the molecular integrals to the basis of "non-perturbed" one-electron functions;
- perform two FS-CC calculations with these integrals at external fields strengths -F and +F:
- estimate TDMs are estimated using the finite-difference-type formula:

$$\boldsymbol{d}_{\eta,if}^{FF} = (E_i - E_f) \lim_{\substack{F_{\eta} \to 0 \\ F_{\eta'} = 0, \eta' \neq \eta}} \frac{\langle \tilde{\psi}_i^{\perp \perp} (-F_{\eta}) | \tilde{\psi}_f (+F_{\eta}) \rangle}{2F_{\eta}} \quad (\eta = x, y, z), \tag{5}$$

where $\tilde{\psi}_i$ and $\tilde{\psi}_f$ are model vectors corresponding to initial and final electronic states, respectively.

Consider the FF calculation of TDMs for the ${}^2S_{1/2} \leftrightarrow {}^2P^o_{1/2}$ and ${}^2S_{1/2} \leftrightarrow {}^2P^o_{3/2}$ transitions in the Rb atom. The basis set and effective core potential employed were taken from [28]; basis set was reduced to [7s7p5d3f2g]. The simplest active space required to describe ${}^2S_{1/2}$, ${}^2P^o_{1/2}$ and ${}^2P^o_{3/2}$ states of Rb comprised 5s- and 5p-spinors (overall 8 spinors, or 4 Kramers pairs).

Firstly, we perform the Hartree-Fock calculation and subsequent transformation of integrals. Note that transformed integrals of one-electron properties (in this case, the dipole moment operator) are stored in the MDPROP unformatted file which should be copied from DIRAC scratch to the working directory:

```
pam --noarch --inp=TRA.inp --mol=Rb.mol --get="MRCONEE MDCINT MDPROP"
```

Other integrals are saved to the MRCONEE (one-electron Fock) and MDCINT (two-electron) unformatted files. Note that the .PRPTRA option as well as the **PROPERTIES/.DIPOLE specification is required in the TRA.inp input file:

```
**MOLTRA
.PRPTRA
.SCHEME
4
.ACTIVE
energy -100.0 20.0 0.5
**PROPERTIES
.DIPOLE
```

These lines are used to ask DIRAC to calculate and transform dipole moment integrals (these integrals are used later to construct the perturbation due to the external field). Also note that the external uniform electric field lowers spherical symmetry of the atom to $C_{\infty v}$.

Now we are ready to run FSCC calculations in EXP-T. At this step we use the oneprop directive to add an external field F contribution to the Fock operator:

$$f'_{pq} = f_{pq} + (d_x)_{pq}F_x + (d_y)_{pq}F_y + (d_z)_{pq}F_z$$

Here we use only the d_z component, stored in the MDPROP file in the ZDIPLEN record. The operator which is added to the Fock matrix must be fully symmetric. The first EXP-T input file (for field strength -F):

```
# title for the task (of type "string")
title "Rb atom -- relativistic EA-CCSD calculation"

# max number of iterations
maxiter 50

# convergence threshold (by cluster amplitudes)
conv 1e-9

# target Fock space sector
sector 0h1p

# active space specification: 8 lowest virtual spinors (5s,5p1/2,5p3/2)
nactp 8

# add the external field contribution to the Fock matrix:
# Fock = Fock + d_z * F_z
# (F_z = 1e-5)
oneprop -1e-5 0.0 "ZDIPLEN"
```

For the other field strength +F it is convenient to reuse two-electron integrals, which are already sorted (the reuse option). One-electron integrals depend on the finite perturbation parameter and must be recomputed. Cluster amplitudes converged at -F can also serve as an excellent initial guess for the calculation at +F. This will lead to significant computational savings. Use the --no-clean option to prevent the deletion of files containing sorted two-electron integrals and converged amplitudes.

The second EXP-T input file (for field strength +F):

```
title "Rb atom -- relativistic EA-CCSD calculation"
maxiter 50
conv 1e-9
sector 0h1p
nactp 8

reuse 2-integrals amplitudes
oneprop +1e-5 0.0 "ZDIPLEN"
```

Run EXP-T and save formatted files HEFF with effective Hamiltonian matrices to the working directory:

```
expt.x --no-clean input_F- | tee ccsd_F-.out
mv scratch/HEFF HEFF1
expt.x --no-clean input_F+ | tee ccsd_F+.out
mv scratch/HEFF HEFF2
```

The electronic spectrum is given at the end of the EXP-T output file. Corresponding lines begin with the @ symbol:

Le	vel	Re(eigenvalue)	•	•	.Re	el eigv,	cm-1	deg	symmetry
0	1	-0.1531234146				0.0	00000	2	1/2+ 1/2-
0	2	-0.0959179975				12555.1	37832	2	1/2+ 1/2-
0	3	-0.0948635671				12786.5	58570	2	1/2+ 1/2-
0	4	-0.0948635506				12786.5	62182	2	3/2+ 3/2-

(compare with experimental values $12578.950 \text{ cm}^{-1}$ and $12816.545 \text{ cm}^{-1}$ [27]; note that the $^2P^o_{3/2}$ state is split in the external electric field).

Finally, we turn to the calculation of transition moments. The input file for the heffman.x utility is as follows (see Sec. 6.1 for details and explanation):

file: HEFF1
file: HEFF2
sector: Oh1p

rep: 1

step: 0.00002
print: 1

Run heffman.x:

heffman.x < ff.inp | tee ff.out

Transition moments and Einstein coefficients:

tran	siti	on	energy, cm^-1	 d ^2	d	osc str	A,10^6 s-1
1	->	2	12555.138	 2.627905	1.62108158	0.100220	10.537579
1	->	3	12786.559	 5.173064	2.27443710	0.200921	21.911672
2	->	3	231.421	 0.000000	0.00001167	0.000000	0.000000

Note: this is only the $|d_z|$ component of the full transition moment d. It should be mentioned that the small, but non-zero value of |d| in the last line is an artifact of the FF approach.

Taking into account the degeneracy of the ${}^2P^o_{3/2}$ state and the spherical symmetry of the Rb atom, the full transition moments |d| and full Einstein coefficients can be calculated:

$$A(^{2}S_{1/2} \leftarrow {^{2}P_{1/2}^{o}}) = 31.6 \text{ s}^{-1}$$

 $A(^{2}S_{1/2} \leftarrow {^{2}P_{3/2}^{o}}) = 32.9 \text{ s}^{-1}$

(compare with experimental values 34.0 s^{-1} and 37.0 s^{-1} [27]).

Results can be improved significantly by extending the basis set and active space [28].

5.5 «High-spin» CCSD for open shell systems

For input/output files see examples/02_highspin

The example considered in this subsection is borrowed from the DIRAC program manual [12]. Let us calculate the energy of the ground (triplet) state of the O₂ molecule.

The DIRAC input file contains directives for the HF calculation and subsequent integrals transformation:

```
(O2.mol)
```

```
test of open-shell CCSD calculation
molecular oxygen at eq distance taken from NIST
automatic symmetry detection: DIRAC will identify the Dinfh group

DIRAC writes spinor occupation numbers to the MRCONEE unformatted file, but only spinors belonging to closed shell (the .CLOSED_SHELL keyword) are labeled as occupied. This is why EXP-T will calculate the energy for the O_2^{2+} cation without manually specified occupation numbers.

EXP-T provides two ways to set the occupation numbers of spinors:

• by setting the number of occupied spinors in each irrep (the occ_irreps keyword). For the example under consideration:

```
occ_irreps 3 2 0 1 0 0 0 0 0 0 0 0 0 0 0 2 2 1 1
```

Note that the 1s-orbitals of oxygen atoms are frozen here, and the corresponding electrons should not be accounted for in the occ_irreps string. In order to set the number of electrons in each irrep correctly, we recommend starting with a calculation for default occupation numbers and finding strings with an irrep order in the output:

```
0 1/2g+
1 1/2g-
2 3/2g+
3 3/2g-
4 5/2g+
5 5/2g-
...
16 1/2u+
17 1/2u-
18 3/2u+
19 3/2u-
20 5/2u+
21 5/2u-
...
```

For the example discussed:

```
- 3 electrons occupy the lowest spinors belonging to the 1/2g+ irrep;
```

```
- 1/2g-, 1/2u+, 1/2u-: 2 electrons in each irrep;
```

- 3/2g-, 3/2u+, 3/2u-: 1 electron in each irrep.

• you can also specify the occupation number for *each* spinor explicitly:

To identify spinors which should be populated in the electronic state under consideration, we again recommend starting the calculation with the default occupation numbers, then interrupting the task, finding information about spinors and restarting the calculation with the correct occupation numbers.

Note that, in fact, non-canonical orbitals are used, therefore the Fock matrix is not diagonal and the vacuum determinant energy $\langle \Phi_0 | H | \Phi_0 \rangle$ is not equal to the SCF energy value obtained before:

```
Total SCF energy = -149.686661451842
...
sorting one-electron integrals ...
Fock matrix reconstruction ...
SCF energy (energy of reference determinant) = -149.718144633810 a.u.
SCF energy (energy of reference determinant) was updated:
```

```
old energy = -149.686661451842 a.u.
new energy = -149.718144633810 a.u.
```

. . .

SCF reference energy = -149.718144633810 CCSD correlation energy = -0.366958682652 Total CCSD energy = -150.085103316462

6 Utility programs

6.1 heffman – manipulations with effective Hamiltonian matrices

The heffman.x program is designed to perform manipulations with FS-RCC effective Hamiltonians matrices. Implemented features are:

- the finite-field technique for transition dipole moments calculations [14, 28, 4];
- extraction of spin-orbit interactions from full-relativistic models by projection [2];
- Pade extrapolation of series of effective Hamiltonians.

heffman.x reads matrices of effective Hamiltonians from formatted files supported by both EXP-T and the latest versions of DIRAC.

- to compute finite-field transition moments [28, 4] two files with effective Hamiltonians must be provided, calculated at field 1 and field 2;
- to separate spin-orbit interactions by projection, two files with effective Hamiltonians must be provided, the first for spin-orbit (nearly) switched off and the second for spin-orbit switched on.

In this case you cannot freeze spinors at the FSCC step!

• to perform Pade extrapolation of the series of effective Hamiltonians, you have to put a sequence of effective Hamiltonians to a single file using the cat command:

```
cat heff_n_eq_1 heff_n_eq_2 heff_n_eq_3 > some_file_name
```

Recall that each Hamiltonian is calculated at its own attenuation parameter n, see Sec. ??. You can also perform extrapolation before TDM or SO calculation, just use such "composite" files with effective Hamiltonians.

Additional input file with options must be redirected to stdin:

```
heffman.x < input_file
```

heffman.x input files are very similar to EXP-T input files, but keywords are separated from their arguments with the ':' symbol, and the symbol '#' at the beginning of a comment must be placed in the first position of the line.

List of keywords:

file: file with the first effective Hamiltonian or with a sequence of heff's to be extrapolated, e.g.

- heff for the first field value:
- heff for the spin-orbit interaction (nearly) switched off;
- simply heff you want to get the eigenstates;
- sequence of heff's you want to Pade-extrapolate.

Syntax: file: <string path-to-first-heff>

If you are doing finite-field transition moment calculations or SO separation, you have to supply the second file (see the next item).

heff for another field value, or heff for the spin-orbit switched on, respectively. If there is no second file, the effective Hamiltonian eigenvectors and eigenvalues are written to the formatted file HEFFEVF.

Syntax: file: <string path-to-second-heff>

sector: the Fock space sector you are interested in (heff files for higher sectors contain several heff matrices).

Syntax: sector: <H>h<P>p

Example: 0h1p, 1h0p, 2h0p, 0h2p, 1h1p.

rep: irreducible representation you are interested in. As a rule, rep: 1 for the fully symmetrical rep.

Syntax: rep: <integer n>

Enumeration of irreps begins from 1!

main: for the FF-TDM calculations or Pade extrapolation: simply the number of lowest states or the range of states of given sector and symmetry you want to see in the output file. For the SO extraction by the projected approximant construction [3] this keyword defines the subspace of states used for projection.

Syntax: main: <integer number> or main: <integer number1>-<integer number2>.

Default: all states.

Example: main: 10 (equivalently, main: 1-10)

[L/M] (optional) to perform Pade extrapolation, you have to indicate which Pade approximant [L/M] should be constructed ([0/1], [1/1], [0/2] etc). You should have L+M+2 effective Hamiltonian matrices to build the [L/M] approximant. You can cut off all states above subspace done by the main keyword (see above); to do this, add the cut keyword.

Syntax: [L/M] [cut]

Default: Padé extrapolation disabled

Example: [0/1] cut

step: only for FF calculations. Difference of field strengths (a.u.) in two finite-field calculations. The presence of this line activates the FF TDM calculation mode (do not use this keyword in other types of calculations).

Syntax: step: <real value>

scale: only for SO calculations. Fraction of effective spin-orbit retained in "scalar" calculations to get good relativistic symmetries (typically of order 10⁻⁴. Omit this line if you do not want to diabatize anything.

Syntax: scale: <real value>

ground: ground state energy (a.u.). Useful only when you have to compute energies with

respect to some state (normally ground) which belongs to another rep or sector.

Syntax: ground: <real energy>

Default: ground: 0.0

print: print level. print: 0 or print: 1 are normally ok; enlarging this number, you

can get any amount of superfluous information listed.

Syntax: print: <integer level>

Default: print: 1

Bloch activates the computation of finite-field transition dipoles with Bloch effective

Hamiltonian eigenvectors (note: TDM matrices will be non-Hermitian, this has no physical meaning). Otherwise, ff computations are performed with des Cloizeaux

effective Hamiltonian eigenvectors ("hermitization").

Syntax: Bloch

Default: "hermitization" is enabled in finite-field calculations

When using any of the techniques implemented in the heffman.x program, please, cite the corresponding paper:

• finite-field transition dipole moment calculations: [4]

• quasidiabatization by projection and SO extraction: [2]

• Pade extrapolation: [3]

Appendix B Temporary files

During the calculation, EXP-T operates with temporary files stored in the *scratch* directory. We recommend to remove these temporary files after every calculation (except for those planned to be used in the future, like the HEFF files or files with cluster amplitudes). All types of temporary files generated by EXP-T are listed and described below.

- HINT one-electron integrals core Hamiltonian matrix + one-particle part of perturbation (if presented). Recommended for removal after calculation.
- VINT-*-*-* two-electron integrals. These files are generated during the integral sorting stage. Recommended for removal after calculation.

Approximate number of files: $\sim N_b^4$ (N_b – number of blocks into which the whole set of spinors is divided by symmetry and the tilesize parameter)

- *.sb single symmetry block of molecular integrals/cluster amplitudes. It is just a part of a diagram. During the calculation each file is mapped to some structure in RAM. Recommended for removal after calculation.
 - Approximate number of files: $\sim 10 \times N_b^4$ for CCSD, $\sim N_b^6$ for CCSDT-n and CCSDT models can be very large!
- *.dg file containing diagram. Diagram files containing cluster amplitudes (t1c.dg, t2c.dg etc) can be used in subsequent calculations when constructing the initial approximation to amplitudes (see Sec. 4, keyword reuse).
- HEFF formatted file containing effective Hamiltonian matrices. These files can be read by the heffman.x utility program used to perform Padé extrapolation of series of effective Hamiltonians [3], finite-field transition moments calculations [28, 4], spin-orbit coupling calculations [2].
- *DIPLEN formatted files with dipole moment integrals (just its electronic part) in the basis of molecular spinors.
- MVCOEF** binary files containing model vectors expanded in the basis of model determinants. These files are used to organize data flow inside EXP-T in the most convenient and logical manner; model vectors are used for calculation of model-space approximations of TDMs and "quasi-natural" spinors, etc.

Appendix C Symmetry and irreducible representations

This section lists the names of irreducible representations (irreps) used in EXP-T.

- For nonrelativistic groups, irrep is determined by the spatial symmetry (Mulliken notation is used) and the M_s value (for $M_s >= 2$ only symbol 2 is used);
- For relativistic double groups we use Mulliken-type notation (completely inherited from DIRAC);
- For $U(1) = \overline{C_{\infty v}}$ and $U(1) \times C_i = \overline{D_{\infty h}}$ irreps are determined by Ω values.
